04–06 September 2024

A multifaceted problem

What type of problems are we facing?

- CPU or data access problems
- Identifying the dominant issues: Algorithms, implementation, parallelisation, ...

What transformations to apply?

- Compiler switches, Partial/full vectorization
- Loop blocking/array restructuring, If removal, Full unroll
- Binary transforms (prefetch),
- ...

Making the **best use** of the machine features
Finding the **most rewarding** issues to be fixed

- **40%** total time, expected **10%** speedup

- → TOTAL IMPACT: **4%** speedup

- **20%** total time, expected **50%** speedup

- → TOTAL IMPACT: **10%** speedup

→ **Need for dedicated and complementary tools**

Our Approach

Nobody wants problems everybody wants solutions 😊

- Focusing on the knobs that code developers can operate:
 - Compiler flags and runtime settings
 - Code restructuring
 - Data restructuring
- Helping the user in using these knobs

→ Instead of pinpointing problems, guiding the user towards a way to address them.

Philosophy: Analysis at Binary Level

- Compiler optimizations increase the distance between the executed code and the source code
- Source code instrumentation may prevent the compiler from applying certain transformations

→ What You Analyse Is What You Run

MAQAO: Modular Assembly Quality Analyzer and Optimizer

Objectives:

- Characterizing performance of HPC applications
- Focusing on performance at the **core level**
- **Guiding users** through the optimization process
- Estimating return on investment (**R.O.I.**)

Characteristics:

- **Modular tool** offering complementary views
- Support for **x86-64** and **Aarch64** (beta version)
 - Work in progress on GPU support
- LGPL3 Open Source software
- Developed at UVSQ since 2004
- Binary release available as a **static executable**

Success stories

Optimizing industrial and academic HPC applications:

- QMC=CHEM (IRSAMC)
 - Quantum chemistry
 - Speedup: **> 3x**
 - Optimization: moved invocations of functions with identical parameters out of the loop body
- Yales2 (CORIA)
 - Computational fluid dynamics
 - Speedup: **up to 2.8x**
 - Optimization: removing double structure indirections
- Polaris (CEA)
 - Molecular dynamics
 - Speedup: **1.5x – 1.7x**
 - Optimization: enforcing loop vectorization through compiler directives
- AVBP (CERFACS)
 - Computational fluid dynamics
 - Speedup: **1.08x – 1.17x**
 - Replaced divisions by reciprocal multiplications
 - Complete unrolling of loops with a small number of iterations

Partnerships

MAQAO is part of the POP Centre of Excellence

- Provides performance optimisation and productivity services for academic and industrial codes
- <https://pop-coe.eu/>

MAQAO has been funded by UVSQ, Intel and CEA (French department of energy) through Exascale Computing Research (ECR) and through various European projects (FUI/ITEA: H4H, COLOC, PerfCloud, ELCI, POP2 CoE, TREX CoE, etc...)

Provided core binary analysis and instrumentation capabilities and features for other tools:

- TAU performance tools with MADRAS patcher through MIL (MAQAO Instrumentation Language)
 - X86_64 only, aarch64 under development
- Intel Advisor

More on MAQAO

MAQAO website: www.maqao.org

- Email: contact@maqao.org

MAQAO Main Features

Binary layer

- Builds internal representation from binary
 - Construct high level structures (CFG, DDG, SSA, ...)
 - Links binary instructions to source code
 - Δ A single source loop can be compiled as multiple assembly loops → Affecting unique identifiers to loops
- Allows patching through binary rewriting

Profiling

- LProf: Lightweight sampling-based Profiler operating at process, thread, function and loops level

Static analysis

- CQA (Code Quality Analyzer): Evaluates the quality of the binary code and offers hints for improving it

Performance view aggregation module: ONE View

- Goal: Guiding the user through the analysis & optimization process.
- Synthesizes information provided by different MAQAO modules
- Automates execution of experiments invoking other MAQAO modules and aggregates their results to produce high-level reports in HTML or XLSX format

MAQAO LProf: Lightweight Profiler

Goal: Lightweight localization of application hotspots

Features:

- **Lightweight**
- **Sampling** based
- Access to hardware counters
- Analysis at **function** and **loop** granularity

Strengths:

- **Non intrusive:** No recompilation necessary
- **Low overhead**
- Agnostic with regard to parallel runtime

MAQAO CQA: Code Quality Analyzer

Goal: **Assist developers** in improving code performance

Features:

- Static analysis: **no execution** of the application
- Allows **cross-analysis** of/on multiple architectures
- Evaluates the **quality** of compiler generated code
- Proposes **hints and workarounds** to improve quality/performance
- **Loops centric**
 - In HPC, loops cover most of the processing time
- Targets **compute-bound** codes

The screenshot displays the 'Static Reports' section of the MAQAO CQA tool. It is titled 'CQA Report' and shows the location of the analyzed loop: /tmp/NPB3.3.1-MZ/NPB3.3-MZ-MPI/BT-MZ/z_solve.f:415-423. Under 'Path 1', it indicates that 2% of peak computational performance is used (0.77 out of 32.00 FLOP per cycle (GFLOPS @ 1GHz)). There are four tabs: 'gain', 'potential', 'hint', and 'expert'. The 'Code clean check' section reports a slowdown caused by scalar integer instructions, suggesting a 1.14x speedup by removing them. The 'Workaround' section provides three suggestions: reorganizing arrays, using 'allocatable' arrays, and limiting indirect addressing. The 'Vectorization' section notes that the loop is not vectorized and suggests an 8.00x speedup by vectorizing. Its 'Workaround' section offers advice on compiler options, vector dependencies, and loop ordering. Finally, the 'Execution units bottlenecks' section states that no bottlenecks were found, but expert reports may contain more details.

Static Reports

▼ CQA Report

The loop is defined in /tmp/NPB3.3.1-MZ/NPB3.3-MZ-MPI/BT-MZ/z_solve.f:415-423

▼ Path 1

2% of peak computational performance is used (0.77 out of 32.00 FLOP per cycle (GFLOPS @ 1GHz))

gain potential hint expert

Code clean check

Detected a slowdown caused by scalar integer instructions (typically used for address computation). By removing them, you can lower the cost of an iteration from 65.00 to 57.00 cycles (1.14x speedup).

Workaround

- Try to reorganize arrays of structures to structures of arrays
- Consider to permute loops (see vectorization gain report)
- To reference allocatable arrays, use "allocatable" instead of "pointer" pointers or qualify them with the "contiguous" attribute (Fortran 2008)
- For structures, limit to one indirection. For example, use a_b%c instead of a%b%c with a_b set to a%b before this loop

Vectorization

Your loop is not vectorized. 8 data elements could be processed at once in vector registers. By vectorizing your loop, you can lower the cost of an iteration from 65.00 to 8.12 cycles (8.00x speedup).

Workaround

- Try another compiler or update/tune your current one:
 - use the vec-report option to understand why your loop was not vectorized. If "existence of vector dependences", try the IVDEP directive. If, using IVDEP, "vectorization possible but seems inefficient", try the VECTOR ALWAYS directive.
- Remove inter-iterations dependences from your loop and make it unit-stride:
 - If your arrays have 2 or more dimensions, check whether elements are accessed contiguously and, otherwise, try to permute loops accordingly: Fortran storage order is column-major: do i do j a(i,j) = b(i,j) (slow, non stride 1) => do i do j a(j,i) = b(i,j) (fast, stride 1)
 - If your loop streams arrays of structures (AoS), try to use structures of arrays instead (SoA): do i a(i)%x = b(i)%x (slow, non stride 1) => do i a%x(i) = b%x(i) (fast, stride 1)

Execution units bottlenecks

Found no such bottlenecks but see expert reports for more complex bottlenecks.

“What If” Scenarios: Vectorization

Code “Clean”

- Generate an Assembly “Clean” variant : **keep only FP Arithmetic and Memory operations, suppress all other**
- Generate a CQA Performance estimate on the “Clean” Variant

Code “FP Vector”

- Generate an Assembly “FP Vector” variant : **only replace scalar FP Arithmetic by Vector FP Arithmetic equivalent.** Generate additional instructions to fill in Vector Registers.
- Generate a CQA Performance estimate

Code “Full Vector”

- Generate an Assembly “Full Vector” variant : **replace both scalar FP Arithmetic and FP Load/Store by their Vector equivalent.**
- Generate a CQA Performance estimate

All of these “What If Scenarios” are generated in a fully static manner.

MAQAO ONE View: Performance View Aggregator

Automating the whole analysis process

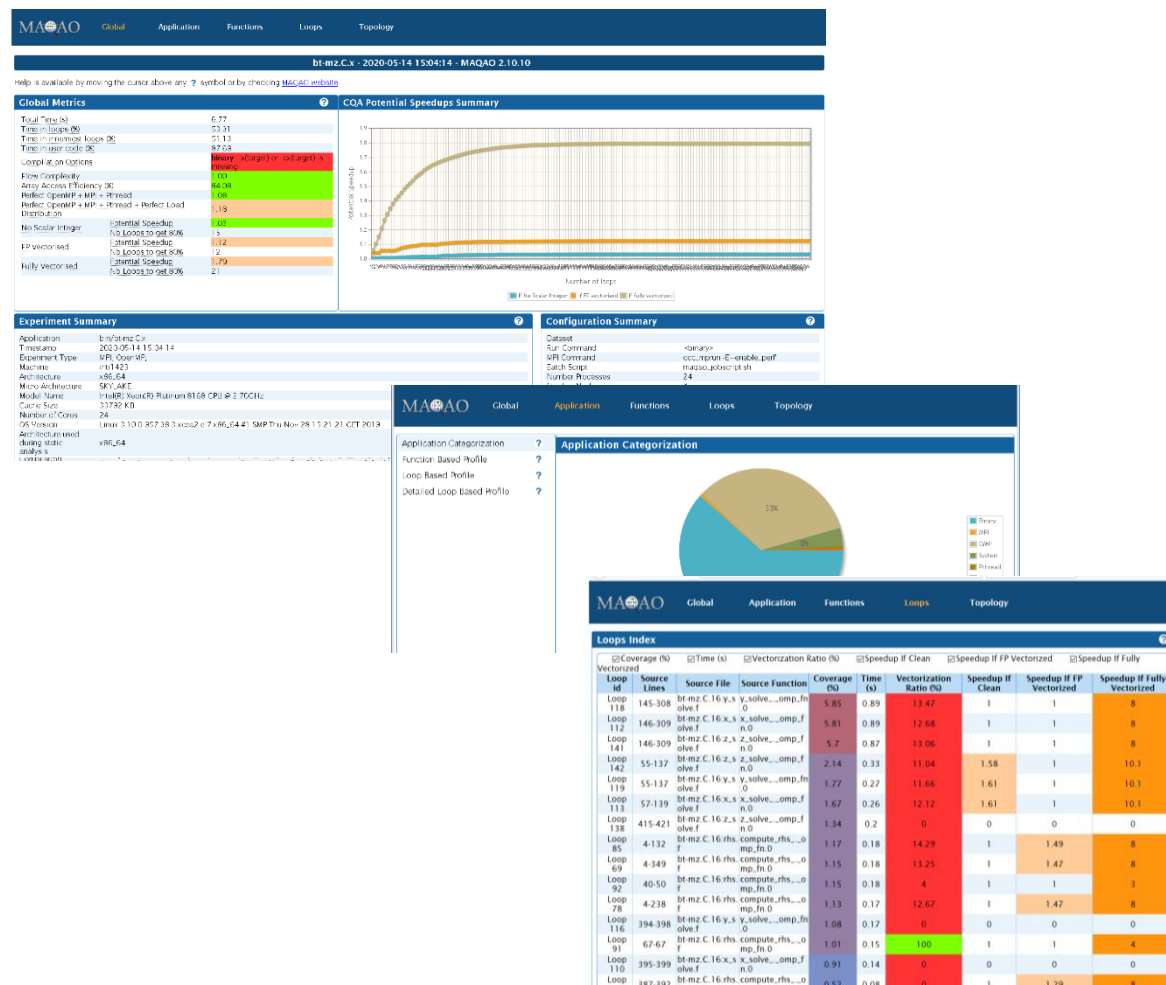

- Invoke multiple MAQAO modules
- Generate **aggregated performance views**
- Generate a report in HTML format

Main steps:

- Invokes LProf to **identify hotspots**
- Invokes CQA on **hotspots**

Available results:

- **Speedup** predictions
- **High-level** summary
- Global **code quality** metrics
- **Hints** for improving performance
- Parallel **efficiency** analysis

ONE View Reports Levels

ONE VIEW ONE

- Requires a single run of the application
- Profiling of the application using LProf
- Static analysis using CQA

Scalability mode

- Multiple executions with varying parallel configurations
- Allows to evaluate scalability or parallel behaviour of applications

Comparison mode

- Comparison of multiple runs (iso-binary or iso-source)
- Allows to compare performance across different datasets, compilers, or hardware platforms

Stability mode

- Multiple runs with identical parameters
- Allows to assess the stability of execution time

Analysing an application with MAQAO

ONE View execution

- Provide all parameters necessary for executing the application
 - Parameters can be passed on the command line or as a configuration file
 - Parameters include binary name, MPI commands, dataset directory, ...

```
$ maqao oneview --create-report=one --executable=bt-mz.C.16 --mpi_command="mpirun -n 16"
```

```
$ maqao oneview --create-report=one --config=my_config.json"
```

- Analyses can be tweaked if necessary
 - Report level **one** corresponds to lightweight profiling (**LProf**) and code quality analysis (**CQA**)
- ONE View can reuse an existing experiment directory to perform further analyses
- Results available in HTML format by default
 - XLS spreadsheets and textual output generation are also available

Online help is available:

```
$ maqao oneview --help
```

Backup Slides

Performance analysis and optimisation

Where is the application spending most execution time and resources?

Why is the application spending time there?

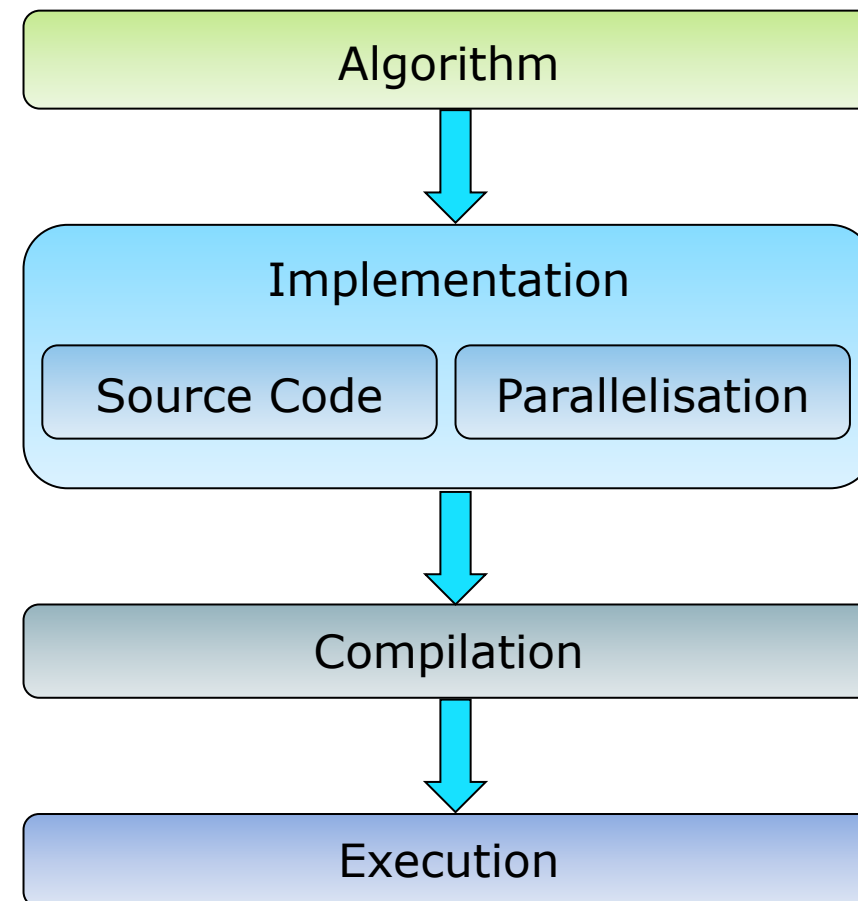

- Algorithm, implementation, runtime or hardware?
- Data access or computation?

How to improve the application?

- At which step(s) of the workflow or dev process?
- What additional information is needed?

How much gain can be expected?

- At what cost?

Motivating example

Code of a loop representing ~10% walltime

```
do j = ni + nvalue1, nato

  nj1 = ndim3d*j + nc ; nj2 = nj1 + nvalue1 ; nj3 = nj2 + nvalue1
  u1 = x11 - x(nj1) ; u2 = x12 - x(nj2) ; u3 = x13 - x(nj3)
  rtest2 = u1*u1 + u2*u2 + u3*u3 ; cnij = eci*qEold(j)
  rij = demi*(rvwi + rvwalc1(j))
  drtest2 = cnij/(rtest2 + rij) ; drtest = sqrt(drtest2)
  Eq = qq1*qq(j)*drtest
  ntj = nti + ntype(j)
  Ed = ceps(ntj)*drtest2*drtest2*drtest2
  Eqc = Eqc + Eq ; Ephob = Ephob + Ed
  gE = (c6*Ed + Eq)*drtest2 ; virt = virt + gE*rtest2
  u1g = u1*gE ; u2g = u2*gE ; u3g = u3*gE
  g1c = g1c - u1g ; g2c = g2c - u2g ; g3c = g3c - u3g
  gr(nj1, thread_num) = gr(nj1, thread_num) + u1g
  gr(nj2, thread_num) = gr(nj2, thread_num) + u2g
  gr(nj3, thread_num) = gr(nj3, thread_num) + u3g

end do
```

Where are the bottlenecks?

Motivating example

Code of a loop representing ~10% walltime

```

do j = ni + nvalue1, nato
  nj1 = ndim3d*j + nc ; nj2 = nj1 + nvalue1 ; nj3 = nj2 + nvalue1
  u1 = x11 - x(nj1) ; u2 = x12 - x(nj2) ; u3 = x13 - x(nj3)
  rtest2 = u1*u1 + u2*u2 + u3*u3 ; cnij = eci*qEold(j)
  rij = demi*(rvwi + rvwalc1(j))
  drtest2 = cnij/(rtest2 + rij) ; drtest = sqrt(drtest2)
  Eq = qq1*qq(j)*drtest
  ntj = nti + ntype(j)
  Ed = ceps(ntj)*drtest2*drtest2*drtest2
  Eqc = Eqc + Eq ; Ephob = Ephob + Ed
  gE = (c6*Ed + Eq)*drtest2 ; virt = virt + gE*rtest2
  u1g = u1*gE ; u2g = u2*gE ; u3g = u3*gE
  g1c = g1c - u1g ; g2c = g2c - u2g ; g3c = g3c - u3g
  gr(nj1, thread_num) = gr(nj1, thread_num) + u1g
  gr(nj2, thread_num) = gr(nj2, thread_num) + u2g
  gr(nj3, thread_num) = gr(nj3, thread_num) + u3g
end do

```

1) High number of statements

2) Non-unit stride accesses

3) Indirect accesses

4) DIV/SQRT

5) Reductions

6) Variable number of iterations

- 1) High number of statements
- 2) Non-unit stride accesses
- 3) Indirect accesses
- 4) DIV/SQRT
- 5) Reductions
- 6) Variable number of iterations

Which is the dominant one?

MAQAO Main structure

Useful notions

SIMD/Vectorization/Data Parallelism

- Scalar pattern: $a[i] = b[i] + c[i]$
- Vector pattern: $a(i, i + 8) = b(i, i + 8) + c(i, i + 8)$
- Benefits : increases memory bandwidth and **IPC**
- Example implementations :
 - ARM : Neon, SVE
 - x86 : SSE, AVX, AVX512

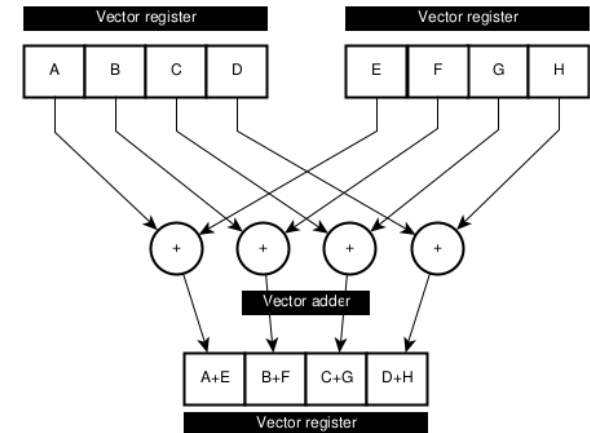

Memory and caches

- Computations are in general faster than memory accesses
- Alignment/Contiguity of memory (x86) :
posix_memalign, aligned_alloc, ...
- Caches: L1, L2, L3, ...

Scalar addition

Vector addition

Crossing cacheline boundary

Unaligned memory access

MAQAO CQA: Main Concepts

Applications exploit at best 5 to 10% of the peak performance.

Main elements of analysis:

- Peak performance
- Execution pipeline
- Resources/Functional units

Key performance levers for core level efficiency:

- Vectorization
- Avoiding high latency instructions if possible (DIV/SQRT)
- Guiding the compiler code optimization
- Reorganizing memory and data structures layout

Same instruction – Same cost

**Process up to
8X data**

MAQAO CQA: Guiding the compiler and implementation hints

Compilers can be driven using flags, pragmas, and keywords:

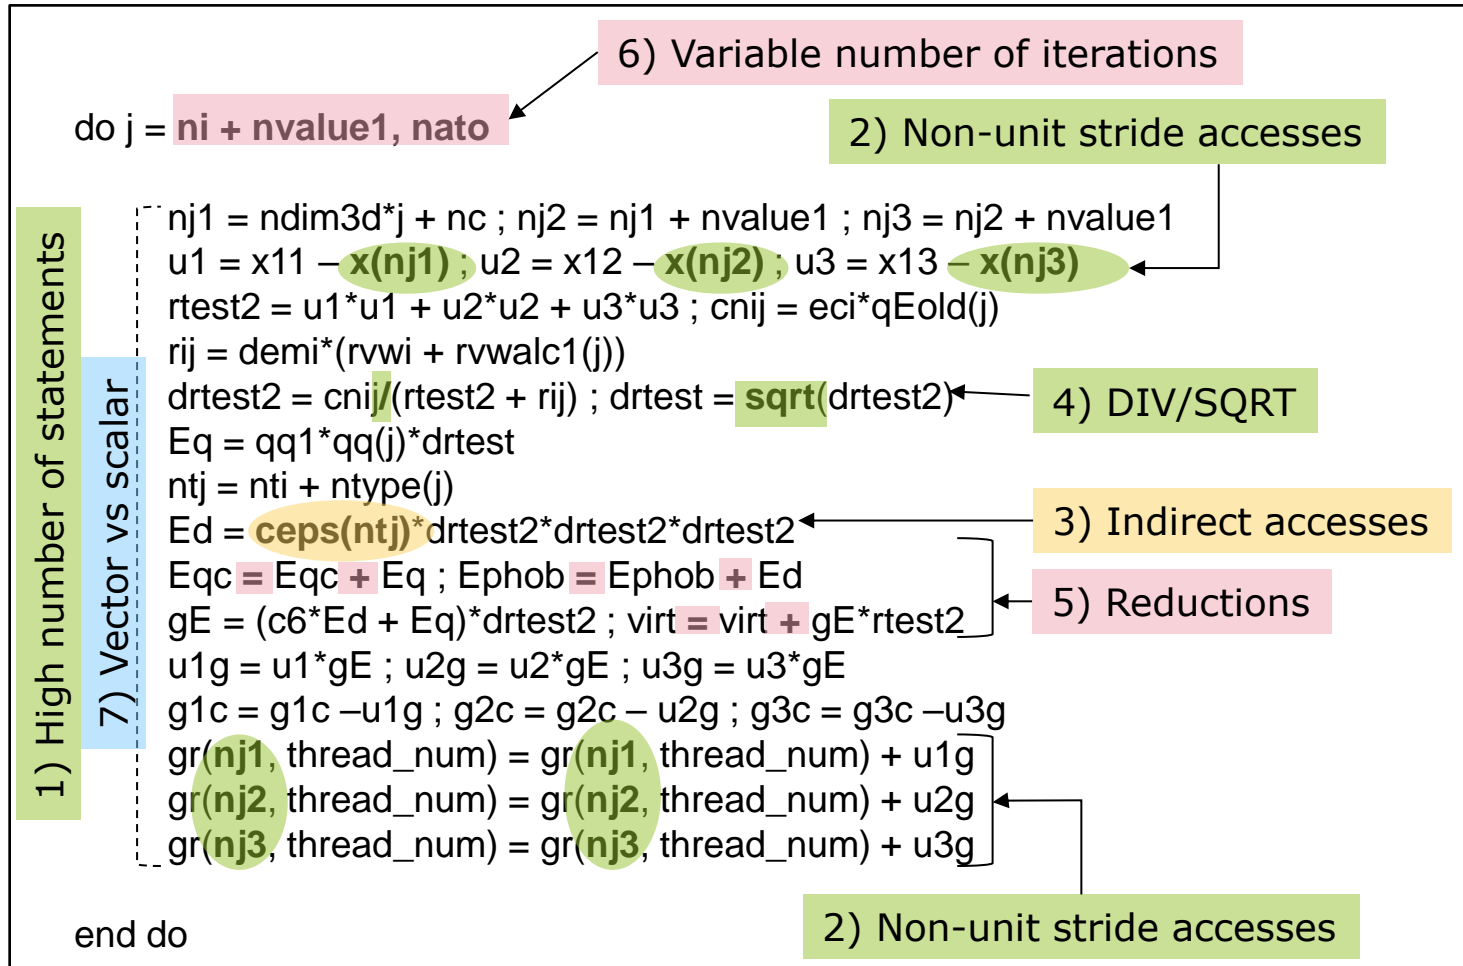

- Ensuring full use of architecture capabilities (e.g. using flag `-xHost` on AVX capable machines)
- Forcing optimizations (unrolling, vectorization, alignment, ...)
- Bypassing conservative behaviour when possible (e.g. 1/X precision)

Hints for implementation changes:

- Improve data access patterns
 - Memory alignment
 - Loop interchange
 - Changing loop strides
 - Reshaping arrays of structures
- Avoid instructions with high latency (SQRT, DIV, GATHER, SCATTER, ...)

Application to Motivating Example

Issues identified by CQA

CQA can detect and provide hints to resolve most of the identified issues:

- 1) High number of statements
- 2) Non-unit stride accesses
- 3) Indirect accesses
- 4) DIV/SQRT
- 5) Reductions
- 6) Variable number of iterations
- 7) Vector vs scalar

Analysing an application with MAQAO

MAQAO modules can be invoked separately for advanced analyses

- LProf
 - Profiling

```
$ maqao lprof xp=exp_dir --mpi-command="mpirun -n 16 -ppn 4" ppn=4 -- ./bt-mz.C.16
```

- Display functions profile

```
$ maqao lprof xp=exp_dir -df
```

- Displaying the results from a ONE View run

```
$ maqao lprof xp=oneview_xp_dir/tools/lprof_npsu -df
```

- CQA

```
$ maqao cqa loop=42 bt-mz.C.16
```

Online help is available:

```
$ maqao lprof --help
```

```
$ maqao cqa --help
```

Loops Profiling Summary

Identifying loop hotspots

- Vectorisation information
- Potential speedup by optimisation
 - No scalar integer: Removing address computations
 - FP Vectorised: Vectorising floating-point computations
 - Fully Vectorised: Vectorising floating-point computations and memory accesses
 - Perfect Load Balancing: Optimal balance across all threads

MAAO Global Application Functions **Loops** Topology

Show Full Profile Open Expert Summary

Loops Index

73 loops have been discarded from the report because their coverage is lower than the threshold set by *object_coverage_threshold* (0.01%). It represents about 0% of the application. To include them, change the value of *object_coverage_threshold* in the experiment directory configuration file, then rerun the command with the additional parameter *--force-static-analysis*

The analysis results are displayed in a sidebar on the right, including:

- Coverage:** 4.79%
- Function:** [matmul_sub](#)
- Source file and lines:** solve_subs.f:71-175
- Module:** bt-mz.C.16
- Description:** The loop is defined in /ccc/dsku/nfs-server/user/cont001/ocre/valensic/NPB3.3.1-MZ/NPB3.3-MZ-MPI/BT-MZ/solve_subs.f:71-175. It is main loop of related source loop which is unrolled by 2 (including vectorization).
- Code clean check:** Detected a slowdown caused by scalar integer instructions (typically used for address computation). By removing them, you can lower the cost of an iteration from 27.00 to 25.00 cycles (1.08x speedup).
- Workaround:**
 - gain potential hint expert**
 - FMA:** Presence of both ADD/SUB and MUL operations.
 - Workaround:**
 - Use parentheses in arithmetic expressions to enable your compiler to use a valid FMA (MUL then ADD then MUL).
 - Use contiguous storage (e.g., do i do j) to extend it into stride-1 elements accessed regularly: Fortran storage order 1) => do i do j
 - Use structures of arrays of type real (e.g., a(i) = b%x(i)) to extend it into stride-1 elements accessed regularly: Fortran storage order 1) => do i do j
 - Use contiguous storage (e.g., do i do j) to extend it into stride-1 elements accessed regularly: Fortran storage order 1) => do i do j
 - Use structures of arrays of type real (e.g., a(i) = b%x(i)) to extend it into stride-1 elements accessed regularly: Fortran storage order 1) => do i do j

The main content area provides detailed analysis for the selected loop:

- Type of elements and instruction set:** 195 SSE or AVX instructions are processing arithmetic or math operations on double precision FP elements in scalar mode (one at a time).
- Matching between your loop (in the source code) and the binary loop:** The binary loop is composed of 195 FP arithmetical operations:
 - 70: addition or subtraction
 - 125: multiply
 The binary loop is loading 1760 bytes (220 double precision FP elements). The binary loop is storing 1632 bytes (204 double precision FP elements).
- Arithmetic intensity:** Arithmetic intensity is 0.06 FP operations per loaded or stored byte.
- Unroll opportunity:** Loop is data access bound.
- Workaround:** Unroll your loop if trip count is significantly higher than target unroll factor and if some data references are common to consecutive iterations. This can be done manually. Or by recompiling with -funroll-loops and/or -floop-unroll-and-jam.

Application to Motivating Example

Vectorization

Your loop is partially vectorized.
Only 28% of vector register length is used (average across all SSE/AVX instructions).
By fully vectorizing your loop, you can lower the cost of an iteration from 57.00 to 21.50 cycles (2.65x speedup).
51% of SSE/AVX instructions are used in vector version (process two or more data elements in vector registers):

- 24% of SSE/AVX loads are used in vector version.
- 0% of SSE/AVX stores are used in vector version.

Since your execution units are vector units, only a fully vectorized loop can use their full power.

Proposed solution(s):

- Try another compiler or update/tune your current one:
 - use the `vec-report` option to understand why your loop was not vectorized. If "existence of vector dependences", try the `IVDEF` directive. If, using `IVDEF`, "vectorization possible but seems inefficient", try the `VECTOR ALWAYS` directive.
- Remove inter-iterations dependences from your loop and make it unit-stride:
 - if your arrays have 2 or more dimensions, check whether elements are accessed contiguously and, otherwise, try to permute loops accordingly:
Fortran storage order is column-major: `do i do j a(i,j) = b(i,j)` (slow, non stride 1) => `do i do j a(j,i) = b(j,i)` (fast, stride 1)
 - if your loop streams arrays of structures (AoS), try to use structures of arrays instead (SoA):
`do i a(i)%x = b(i)%x` (slow, non stride 1) => `do i a%x(i) = b%x(i)` (fast, stride 1)

Execution units bottlenecks

Performance is limited by:

- execution of divide and square root operations (the divide/square root unit is a bottleneck)
- execution of INT/FP operations in vector registers (the VPU is a bottleneck)

By removing all these bottlenecks, you can lower the cost of an iteration from 57.00 to 48.00 cycles (1.19x speedup).

Proposed solution(s):

- Reduce the number of division or square root instructions.
If denominator is constant over iterations, use reciprocal (replace `x/y` with `x*(1/y)`). Check precision impact. This will be done by your compiler with `no-prec-div` or `Ofast`.
Check whether you really need double precision. If not, switch to single precision to speedup execution.
- Reduce arithmetical operations on array elements

Potential gain
Hints
Experts only

FMA

Detected 48 FMA (fused multiply-add) operations.
Presence of both ADD/SUB and MUL operations.

Proposed solution(s):
Try to change order in which elements are evaluated (using parentheses) in arithmetic expressions containing both ADD/SUB and MUL operations to enable your compiler to generate FMA instructions wherever possible.
For instance `a + b*c` is a valid FMA (MUL then ADD). However `(a+b)*c` cannot be translated into FMA.

Slow data structures access

Detected data structures (typically arrays) that cannot be efficiently read/written:

- Constant non-unit stride: 1 occurrence(s)
- Irregular (variable stride) or indirect: 1 occurrence(s)

- 1) High number of statements
- 2) Non-unit stride accesses
- 3) Indirect accesses
- 4) DIV/SQRT
- 5) Reductions
- 6) Variable number of iterations
- 7) Vector vs scalar
